

MultiLang AI Conversion Report

File: 3.scala

Here is the concise breakdown of the conversion: ### 1. What changed * **Language Syntax:** The code was converted from **Kotlin** (statically typed, uses `val`/`var` keywords, camelCase, and curly braces) to **Python** (dynamically typed, no declaration keywords, snake_case, and indentation-based blocks). * **Naming Conventions:** Variable names were converted from camelCase (`employeeName`) to snake_case (`employee\_name`) to align with PEP 8 standards. * **Syntax Structure:** Removed static type keywords (`val`/`var`), parentheses around `if` conditions, and block braces `{}` in favor of colons and indentation. ### 2. Logic preserved * The data values remain identical. * The conditional logic (`salary > 50000` AND `isActive`) functions exactly the same. * The calculation (`salary + bonus`) and the sequence of output statements remain unchanged. ### 3. Optimizations * **Readability:** Python's syntax is more concise and readable due to the removal of unnecessary boilerplate (brackets, keywords, and semicolons). * **Maintainability:** By removing explicit type declarations, the code becomes more flexible, allowing for faster prototyping, though it relies on Python's dynamic type system rather than Kotlin's compile-time safety.
